Context is everything

On the knowledge base as the real difference

From an MCP that sends agents to the knowledge base to an SRE agent that runs entirely locally.

It sounded done ten times

The procedure was already there. The agent had not looked it up.

Nobody could trace where the answer came from.

I

Documented

it was already there

II

Made up

sounded done ten times

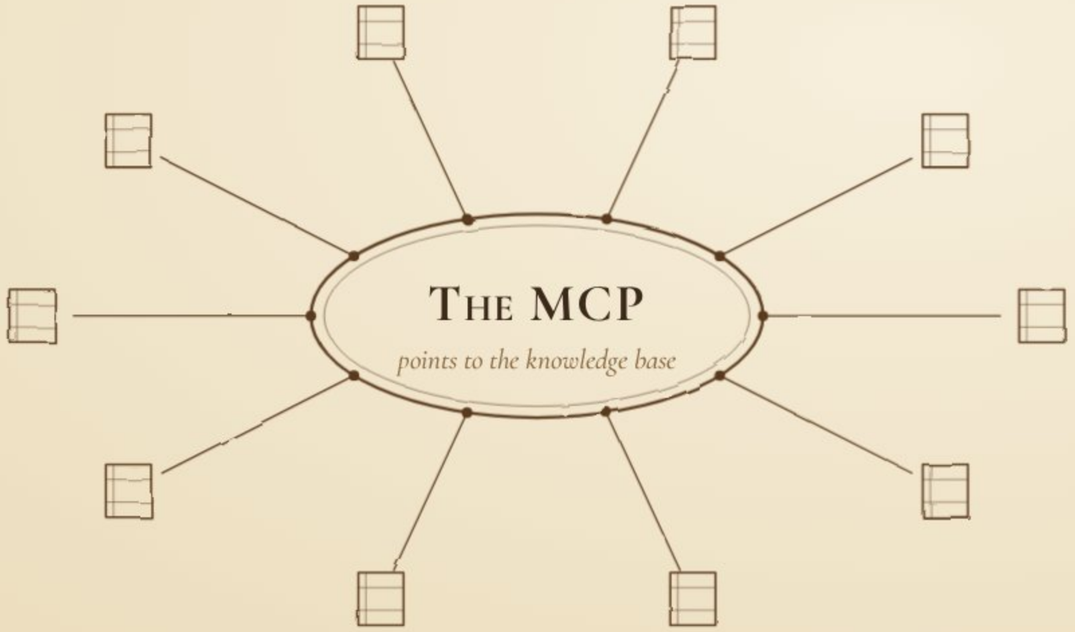

Context (management) is everything

The model had the wrong context, or really no context at all.

The answer is an MCP

You load it, and it sends the agent to the knowledge base. Where you start a session, or what you use the pattern for, then doesn't matter.

On a platform, for example

An agent that can modify its own cage is not in a cage.

I

What goes in

knowledge base first

II

Order

again with every prompt

III

What stays out

the cage stays shut

Since then

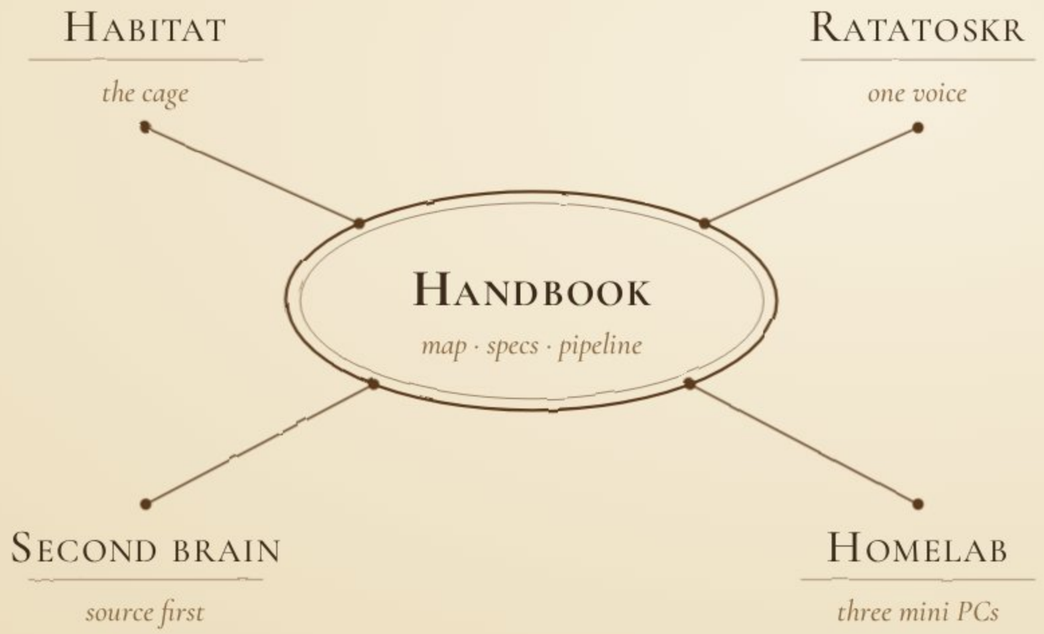

An agent hardly ever makes up such a procedure.

Not because the model got better, but because the context did.

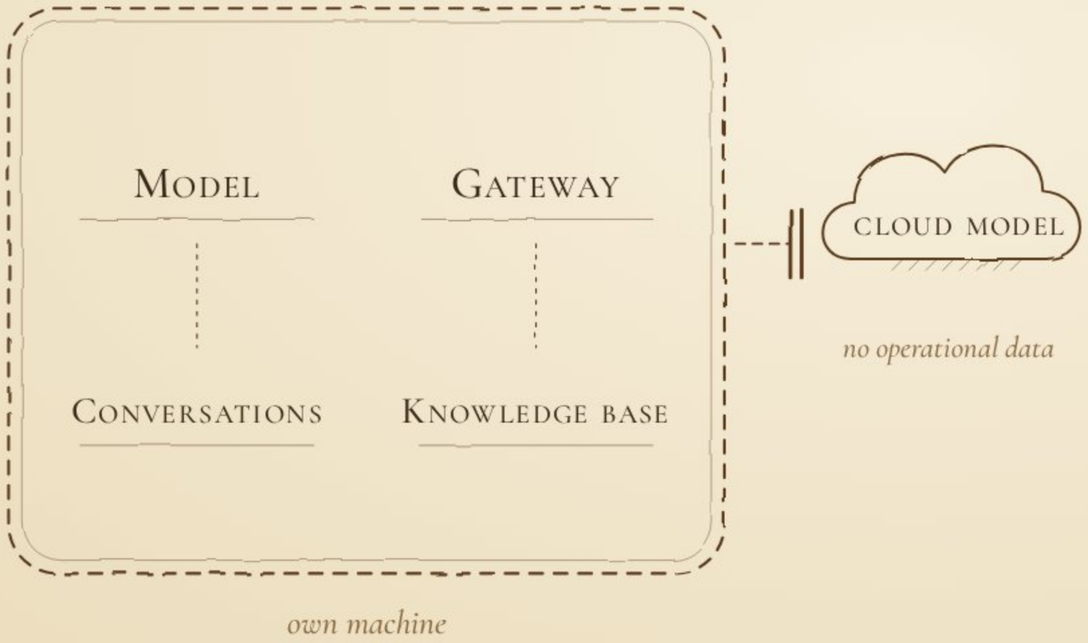

At home: the same pattern

The agent starts at the knowledge base and stays within boundaries it cannot move itself.

SREna: entirely local

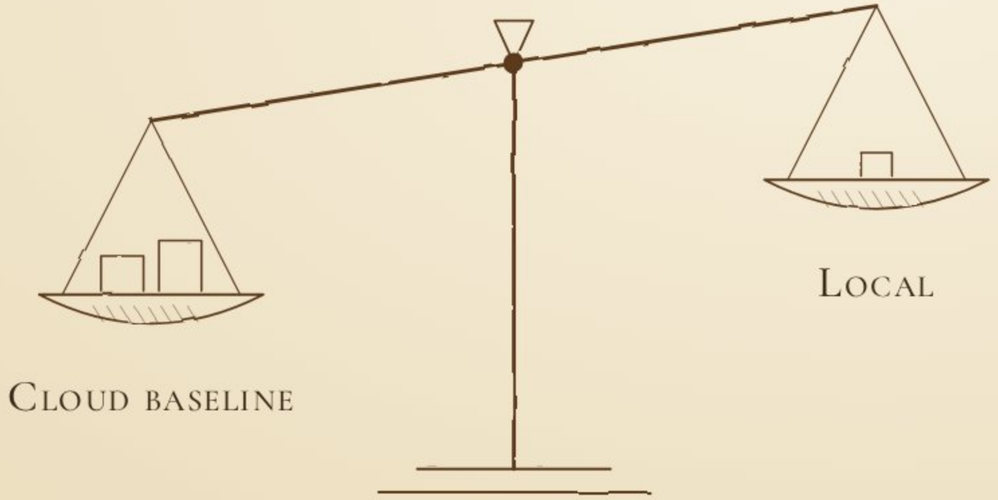

Logs, incidents and runbooks: exactly the context you least want to send out the door.

Honest: the evaluation phase

No users yet. The local model does not reach the cloud baseline yet.

The model choice will be made in the first quarter of 2027.

not yet in balance

Gold, silver, bronze

What is marked as gold weighs more, and she is honest about where her answer comes from.

The idea is borrowed from Google SRE.

I

Gold

confirmed by a human

II

Silver

from a source, unchecked

III

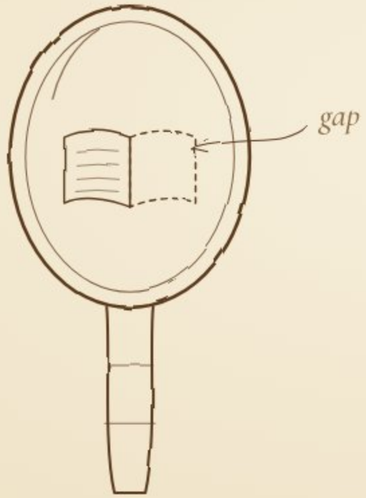

Bronze

pure AI

An honest mirror

A small model fills gaps too, but worse. That is what makes them visible.

an honest mirror of your context

What a local model teaches you

Without a baseline, every impression is a feeling.

I

Address

a missing or wrong source

II

Budget

the context window is finite

III

Bound it

less room, less guessing

IV

Key

permissions are context too

V

Measure

pin it all, measure on your own machine

The biggest lesson

The knowledge base is what prevents hallucination, not the model.

Sovereignty

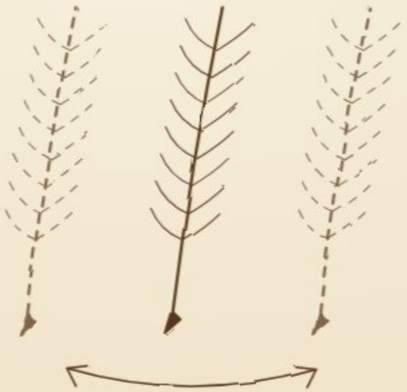

Whoever owns the context can replace the model.

The context simply comes along.

Context

yours, in git

Model

replaceable

Context (management) is everything

The whole story is on westerweel.work.

P.S. Does anyone have a machine with a lot of memory looking for a good home? My homelab would love to join in.

In your organisation?

Would you like this talk or a workshop at your place?

Get in touch via LinkedIn or mark@westerweel.work.
